The viewer tool on other computers

October 2026

Good news: The tool should now work on any computer

First time: two steps

1. install `uv` (and `git`) if missing: one command
2. launch the viewer with the command below, and choose the data folder once

- no Python and no library to install by hand

Afterwards: one command

- the same launch command
- the data folder is remembered
- always the latest code from github.

```
uvx -from git+https://github.com/matteodisante/xc-viewer xc-viewer
```

Bad news: running the viewer on the CFM laptop

1. Personal laptops

- install `uv`, one command
- simple and fast
- the data must sit on the laptop: about 120 GB today

2.CFM laptops

- **implemented**: one command fetches the code from github and installs the packages. Always up to date, but not compliant with the policy ?
- **compliant route?**: an environment (Python, libraries) requested for each laptop?
- even then, the code probably cannot come from the aforementioned github repo.
- a new feature needs new libraries: new authorizations, possibly refused. Development is limited.

Option 2 is operational, but I do not think it can be used on the CFM laptops.

Developing the viewer on CFM laptops

Today: my personal Mac

- personal Claude Code, with the code of the viewer and of every analysis
- it knows the whole situation and reuses the functions/context of the analyses
- a new feature is simpler, faster, more effective

CFM laptops

- Claude without internet access
- no context of the other repositories, where the analyses are developed
- the personal github account cannot be used.

Without the context of the analyses, every new feature is harder to build.
